Examples

Let x be an array of decision variables:

- all. different
- nvalue
- global. cardinality
- element
- bin_packing, knapsack
- cumulative, disjunctive
- circuit, subcircuit
- lex_lesseq
- regular, table
- Checklist COCP/M4CO 3

The all_different (X) constraint holds if and only if all the elements of X take distinct values:

forall(i,j in index_set(X) where i < j)(X[i] != X[j])</pre>

■ The count (X, v) >= c constraint holds if and only if the number of occurrences in X of v is at least c, where v and c can be decision variables:

sum(i in index_set(X))(X[i] = v) >= c

Definition

A definition of a constraint predicate is its semantics, stated in MiniZinc in terms of usually simpler constraint predicates.

Motivation

all. different

nvalue

global. cardinality

element

bin_packing, knapsack

cumulative, disjunctive

circuit, subcircuit

lex_lesseq regular, table

Checklist COCP/M4CO 3

Examples

See some MiniZinc-provided default definitions at slide 4.

Definition

Each use of a predicate is decomposed during flattening by inlining either its MiniZinc-provided default definition or an overriding backend-provided solver-specific definition.

Examples

If a predicate γ on arguments X is supported by a solver, then its backend provides $\gamma(X) = \gamma(X)$ as solver-specific definition. UPPSALA UNIVERSITET

Motivation

different

nvalue

global. cardinality

bin_packing.

disjunctive

subcircuit

regular, table Checklist COCP/M4CO 3

knapsack cumulative

Motivation:

- + More compact and intuitive models, because more expressive predicates are available: islands of common combinatorial structure are identified in declarative high-level abstractions.
- + Faster solving, due to better inference and relaxation, enabled by more global information in the model, provided the predicate is a built-in of the used solver.

Enabling constraint-based modelling:

- Constraint predicates over any number of decision variables go by many names: global-constraint predicates, combinatorial predicates, ...
- See the MiniZinc global constraints and the Global-Constraint Catalogue.
- Some predicates cannot be reified, say via bool2int.

Definition (Laurière, 1978)

The all_different (X) constraint holds if and only if all the elements of the array X of decision variables take distinct values.

Its default definition is a conjunction of $\frac{n \cdot (n-1)}{2}$ disequality constraints when x has n elements:

forall(i,j in index_set(X) where i < j)(X[i] != X[j])</pre>

The all_different_except (X, S) constraint allows multiple occurrences of the exception values in the set S.

Examples

- *n*-Queens problem: see Topic 1: Introduction.
- Photo Alignment problem: see Topic 2: Basic Modelling.
- Student Seating problem: see Topic 4: Modelling.
- Object, Shapes, and Colours: see Topic 4: Modelling.

Checklist COCP/M4CO 3

Definition (Pachet and Roy, 1999)

The nvalue(m, X) constraint holds if and only if decision variable m takes the number of distinct values taken by the elements of the array X of decision variables. If array X is 1d and has indices 1...n, then this means:

 $|\{X\,[\,1\,]\,,\ldots,X\,[\,n\,]\,\}|\;=\;m$

The expression nvalue(X) denotes the number of distinct values taken by the elements of the array X of decision variables.

If |X| = n then nvalue (n, X) means all_different (X), but: Always use the most specific available constraint predicate!

Example

Model 2 of the Warehouse Location problem: see Topic 6: Case Studies.

Checklist COCP/M4CO 3

Definition (Régin, 1996)

The global_cardinality (X, V, C) constraint holds if and only if each decision variable C[j] takes the number of elements of the array X of decision variables that take the given *value* V[j]. Variant predicates exist. Add _closed to the predicate name if V is the domain of the variables in X.

Its default definition in MiniZinc includes:

forall(j in index_set(V))(count(X,V[j]) = C[j])

It means all_different (X) if $V = \bigcup_{i} \text{dom}(X[i])$ and $\text{dom}(C[j]) = \{0, 1\}$ for each j, but: Always use the most specific available constraint predicate!

Examples

- Magic Series problem + Student Seating problem
 - + Object, Shapes, and Colours: see Topic 4: Modelling.
- Warehouse Location + Sports Scheduling: see Topic 6: Case Studies.

should be reformulated, due to the shared array \boldsymbol{x} for each j, into:

constraint global_cardinality(X,V,C);

by applying the default definition backwards:

- at worst, it will be applied forwards while flattening;
- at best, the invoked solver has better inference.

This advice holds for each global-constraint predicate, and for all (quantified) constraints over *shared* decision variables.

Checklist COCP/M4CO 3

Definition (Van Hentenryck and Carillon, 1988)

The element (i, X, e) constraint, where:

- X is an array of decision variables,
 - is an integer decision variable, and
- e is a decision variable,

holds if and only if $X[\underline{i}] = e$.

For better model readability, the element predicate should not be used, as the functional form $X[\phi]$ is allowed, even when ϕ is an integer expression involving at least one decision variable.

Motivation all_ different nvalue

global. cardinality

element

bin_packing, knapsack cumulative, disjunctive circuit, subcircuit lex_lesseq

regular, table

Checklist COCP/M4CO 3 **Use:** The element predicate and its functional form $X[\phi]$ help model an unknown element of an array.

Example (Job allocation at minimal salary cost)

Given jobs Jobs and the salaries of work applicants Apps, **find** a work applicant for each job **such that** some constraints (on the qualifications of the work applicants for the jobs, on workload distribution, etc) are satisfied and the total salary cost is minimal:

1 array[Apps] of 0..1000: Salary; % Salary[a] = cost per job to appl. a 2 array[Jobs] of var Apps: Worker; % Worker[j] = appl. allocated job j 3 solve minimize sum(j in Jobs)(Salary[Worker[j]]); 4 constraint ...; % qualifications, workload, etc

Line 3 is equivalent to the less readable formulation, and flattened into it:

array[Jobs] of var 0..max(Salary): Cost; % Cost[j] = salary for job j
constraint forall(j in Jobs)(element(Worker[j],Salary,Cost[j]));
solve minimize sum(Cost);

We do not know at modelling time the worker allocated to each job!

COCP/M4CO 3

Let item i have the given (weight or) volume Vol[i]. Let decision variable Bin[i] denote the bin into which item i is put. Let decision variable Load[b] denote the load (= volume of items) of bin b. The bin_packing_load (Load, Bin, Vol) constraint holds if and only if each Load[b] is the sum of the Vol[i] where Bin[i] equals b. Variant predicates exist (such as bin_packing in the following example).

Example (Balanced academic curriculum problem)

Given, for each course c in Courses, a workload W[c] and a set Pre[c] of prerequisite courses, find a semester Sem[c] in 1...n for each course c in order to satisfy all the course prerequisites under a balanced workload:

1 constraint bin_packing(sum(W) div n, Sem, W); % same load 2 constraint forall(c in Courses, p in Pre[c]) (Sem[p] < Sem[c]);</pre>

A Common Source of Inefficiency in Models

Example

The model snippet

```
Motivation
all_
different
```

nvalue

global. cardinality

element

bin_packing, knapsack

cumulative, disjunctive

circuit, subcircuit

lex_lesseq

regular, table

Checklist COCP/M4CO 3 constraint forall(b in Bins)
 (Load[b] = sum(i in Items where Bin[i] = b)(Vol[i]));

should be reformulated — due to the shared array Bin for each b

and due to the where clause on the decision variables Bin [i] — as follows:

constraint bin_packing_load(Load,Bin,Vol);

There are many incarnations of this pattern:

- Bins = semesters; Items = courses; Bin[i] = semester of course i; Vol[i] = credits for course i; Load[b] = credits for courses in sem. b;
- Bins = staff; Items = tasks; Bin[i] = employee assigned to task i;
 - Vol[i] = reward for task i; Load[b] = income over tasks to employee b.

COCP/M4CO 3

Definition

A precedence constraint of task T_1 on task T_2 requires that T_1 ends before T_2 starts. We say that task T_1 precedes task T_2 .

Example (courtesy Magnus Rattfeldt)

Sample tasks (circles), durations (black numbers), resource requirements (blue numbers), and precedences (orange arrows). Task T7 is a dummy task, as we do not know which of tasks T5 and T6 will end last.

different

nvalue

global_ cardinality

element

bin_packing. knapsack

cumulative. disjunctive 3

4

5

subcircuit lex_lesseq regular. table

Checklist COCP/M4CO 3 Let us temporarily ignore the capacitated global reusable resource: If we have an uncapacitated global reusable resource or each task has enough of its own local reusable resource, then the polynomial-time-solvable problem of finding the earliest ending time, under only the precedence constraints, for performing all the tasks can be modelled using linear inequalities.

Example (continued)

The precedence constraints indicated by the orange arrows on slide 24 are modelled as follows, based on the task durations indicated there in black:

```
1 \text{ constraint } D = [2, 1, 4, 2, 3, 1, 0];
```

```
2 constraint S[1]+D[1] <= S[2] /\ S[1]+D[1] <= S[3]</pre>
          /\ S[1]+D[1] <= S[4] /\ S[2]+D[2] <= S[5]
          /\ S[3]+D[3] <= S[6] /\ S[4]+D[4] <= S[5]
```

```
/ S[5]+D[5] <= S[7] / S[6]+D[6] <= S[7];
```

6 % plug in here the resource constraint of the next slide 7 solve minimize S[7];

Checklist COCP/M4CO 3

Definition (Aggoun and Beldiceanu, 1993)

The cumulative (S, D, R, c) constraint, where each task T_{i} has the starting time S[i], duration D[i], and resource requirement R[i], holds if and only if the resource capacity c is never exceeded when performing the T_{i} .

Note that <u>cumulative</u> does not ensure any precedence constraints between the tasks: these have to be stated separately (as on the previous slide).

Example (end)

ve, ne

To ensure that the global reusable resource capacity of c = 8 units, say, is never exceeded under the resource requirements of the tasks indicated in blue on slide 24, plug the following constraint into the model of the previous slide:

6 constraint cumulative(S,D,[1,3,3,2,4,6,0],8);

different

nvalue global_

element

knapsack

Definition

A non-overlap constraint between tasks T_1 and T_2 requires that either T_1 precedes T_2 or T_2 precedes T_1 (say because both tasks require a resource that is available only for one task at a time). We say that tasks T_1 and T_2 do not overlap in time.

Definition (Carlier, 1982)

The disjunctive (S, D) constraint, where each task T_i has the starting cardinality time S[i] and duration D[i], holds if and only if no two tasks T_i and T_i overlap in time. It is also known as unary. bin_packing.

cumulative. disjunctive

subcircuit

lex_lesseq

regular. table

Checklist COCP/M4CO 3

It has among others the following definitions:

- forall(i, j in 1...n where i< j)</pre>
 - ((S[i] + D[i] <= S[j]) \/ (S[j] + D[j] <= S[i]))
- cumulative(S, D, [1 | i in 1...n], 1)

Always use the most specific available constraint predicate!

Checklist COCP/M4CO 3

Enabling the representation of a circuit in a digraph:

- \blacksquare Let decision variable ${\tt S}\,[\,v\,]$ denote the successor of vertex v in the circuit.
- The domain of S[v] is the set of vertices to which there is an arc from vertex v, plus v itself (for a reason that will become apparent below).

Example

```
enum Vertices = {a,b,c,d};
array[Vertices] of var Vertices: S;
constraint S[a] != d /\ S[d] != c;
```

Assume the decision variables in s take the following values:

- **I** [b, c, d, a]: **one circuit** $a \rightarrow b \rightarrow c \rightarrow d \rightarrow a$
- $\blacksquare \ [c,a,b,d]: \text{ one subcircuit } a \to c \to b \to a \text{ and } S[d]=d$
- [a,b,c,d]: one empty subcircuit: S[v]=v for all v in Vertices
- \blacksquare [c,d,a,b]: two subcircuits, namely $a \to c \to a$ and $b \to d \to b$
- \blacksquare [b,d,a,d]: c \rightarrow a \rightarrow b \rightarrow d is not a (sub)circuit

different

nvalue

element

bin_packing, knapsack

cumulative, disjunctive

circuit, subcircuit

lex_lesseq regular,

table Checklist COCP/M4CO 3

Definition (Laurière'78; Beldiceanu and Contejean'94)

The circuit (S) constraint holds if and only if the arcs $v \to S[v]$ for all v form a Hamiltonian circuit: each vertex is visited exactly once. The subcircuit (S) constraint holds if and only if circuit (S') holds for exactly one possibly empty but non-singleton subarray S' of S, and S[v] = v for all the other vertices v.

Examples (Vehicle routing)

Travelling salesperson problem (generalise this for vehicle routing problems with multiple vehicles or with side constraints):

3 solve minimize sum(c in Cities)(Distance[c,Next[c]]);

4 constraint circuit(Next);

Requiring a directed path from vertex v to vertex w:

constraint subcircuit (S) $/ \ S[w] = v;$ upon adding v to the domain of S[w] if need be.

Many graph constraints, including dpath, exist in MiniZinc.

Regular Expressions and Languages

Definition

Let Σ be an alphabet, that is a finite set of symbols. A regular expression *r* over Σ , and its regular language over Σ , denoted $\mathcal{L}(r)$, are defined as follows:

- \varnothing is a regular expression: $\mathcal{L}(\varnothing) = \varnothing$.
- ϵ is a regular expression: $\mathcal{L}(\epsilon) = \{\epsilon\}.$
- If $\sigma \in \Sigma$, then σ is a regular expression: $\mathcal{L}(\sigma) = \{\sigma\}$.
- If *r* and *s* are regular expressions, then *rs* is a regular expression: $\mathcal{L}(rs) = \{ v \cdot w \mid v \in \mathcal{L}(r) \land w \in \mathcal{L}(s) \}.$
- disjunctive circuit, subcircuit

cumulative.

lex_lesseq

regular, table

Checklist COCP/M4CO 3

- If *r* and *s* are regular expressions, then r|s is a regular expression: $\mathcal{L}(r|s) = \mathcal{L}(r) \cup \mathcal{L}(s)$.
- If *r* is a regular expression, then r^* is a regular expression:

$$\mathcal{L}(r^*) = \{ w^i \mid i \in \mathbb{N} \land w \in \mathcal{L}(r) \}.$$

Checklist COCP/M4CO 3

Definition (Pesant, 2004)

The regular (X, T, q0, A) constraint holds if and only if the values of the 1d array X of decision variables form a string of the regular language accepted by the DFA with alphabet Σ , states Q, transition function T: $Q \times \Sigma \rightarrow Q$, start state q0 $\in Q$, accepting states $A \subseteq Q$. Variants exist, including regular_nfa. The regular (X, r) constraint holds if and only if the values of X form a string of the regular language denoted by the regular expression r.

Example (C?)

1	<pre>enum Alphabet = {s,t}; enum State = {a,b,c,d,e};</pre>
2	array[State,Alphabet] of opt State:
	Transition = [b,c d,<> e,<> <>,b c,e];
3	array[1n] of var Alphabet: X;
4	<pre>constraint regular(X,Transition,a,{d,e});</pre>
5	constraint regular(X, "s s (t s) \star t s (t s s) \star ");

Definition

The table (X, T) constraint holds if and only if the values of the 1d array X of decision variables form a row of the 2d array T of values.

Motivation

element

bin_packing, knapsack

cumulative, disjunctive

circuit, subcircuit

lex_lesseq

regular, table

Checklist COCP/M4CO 3 The 2d array T gives an extensional definition of a new constraint predicate, as opposed to the intensional definition so far for all other constraint predicates. Note that regular and its variants are *intensional* as an automaton or regular expression is *independent* of the length of X.

Example (

If the array X of the regular constraint of the previous slide for the DFA of two slides ago has n=4 decision variables, then that constraint is equivalent to:

```
6 constraint table(X,[| s,s,t,s | t,s,s,s | t,s,t,t |]);
```

Checklist COCP/M4CO 3

Example (The Nonogram Puzzle: model C + data C)

Model:

- Decision variables: An enumeration-type decision variable for each cell, with value w if it is coloured white, and value b if it is coloured blue.
- Constraints: State a regular constraint for each hint. For example, for a hint 2 3 1 on a row or column X of length n ≥ 8, state the constraint regular (X, "w* b{2} w+ b{3} w+ b{1} w*").

See Survey of Paint-by-Number Puzzle Solvers: the straightforward model outlined above fares well, at least with a CP solver, compared to programs.

Checklist COCP/M4CO 3

Example (Nurse Rostering)

Each nurse is assigned each day to one of the following:

- r regular shift (this value is not available on Sundays)
- e extended shift (this value is not available on Sundays)
- s Sunday shift (this value is only available on Sundays)
- day off

The labour union of the nurses imposes the following regulations:

- Monday off after a Sunday shift
- No single extended shifts
- One day off after two consecutive extended shifts

For each nurse n, state the following constraint over the scheduling horizon, starting on a Sunday (and typically 17 weeks longs in Sweden):

regular(Roster[n,..], "(s \circ | e e \circ | r | \circ)*")

Further, a hospital has constraints on nurse presence, on the ${\tt Roster[..,d]}$.

Example (The Kakuro Puzzle: first model)

Model:

- Decision variables: A decision variable for each cell, with domain 1..9.
- Constraints: For each row or column hint K[α] + ··· + K[β] = σ, state all_different (i in α..β) (K[i])
 /\ sum(i in α..β) (K[i]) = σ.

Performance, using a CP solver:

- 22 × 14 Kakuro with 114 hints: 9,638 nodes, 160 s
- 90 × 124 Kakuro with 4,558 hints: ? nodes, ? years

Symptom: The definition as two constraints may give weak inference: for x!=y / x+y=4, CP inference gives x, y in 1..3, not noticing that 2 should be pruned from both domains. We want a custom predicate all_different_sum, constraining up to 9 variables over the domain 1..9.

Checklist COCP/M4CO 3

Example (The Kakuro Puzzle: second model)

New model: Use the regular or table predicate for the conjunction of the all_different and sum-based constraints of each hint?

- For each length-2 hint x+y=4, state regular([x, y], "1 3|3 1"). Note that we have *precomputed* that y != 2 for this particular case of the wanted all_different_sum(X, σ), where X = [x, y] and σ = 2.
- For each length-2 hint y+z=3, state regular([y, z], "1 2|2 1").
- One can also use table instead:

table([x,y],[|1,3|3,1|]) / table([y,z],[|1,2|2,1|]).

- The regular expressions and tables above are not derived parameters, but precomputed solution sets to islands of common combinatorial structure within all Kakuro puzzles. We revisit precomputation in Topic 4: Modelling.
- But what about the length-9 hint $K[\alpha] + \cdots + K[\alpha+8] = 45$? There are 9! = 362,880 solutions to this hint...

global. cardinality

element

bin_packing, knapsack

cumulative, disjunctive

circuit, subcircuit

lex_lesseq

regular, table

Checklist COCP/M4CO 3

Example (The Kakuro Puzzle: second model, end)

New model (end):

- For each length-9 hint K[α] + ··· + K[α+8] = 45, it suffices to state all_different ([K[i] | i in α..α+8], as the sum of 9 distinct non-0 digits is necessarily 45.
- For each length-8 hint K[α] + ··· + K[α+7] = σ, it suffices to state all_different ([K[i] | i in α..α+7] ++ [45-σ]).

• For each hint $K[\alpha] = \sigma$, it suffices to state $K[\alpha] = \sigma$.

Other opportunities for improvement exist.

New performance, using a CP solver:

- 22 × 14 Kakuro with 114 hints: 0 search nodes, 28 ms!
- 90 × 124 Kakuro with 4,558 hints: 0 nodes, 345 ms!

Published diabolically hard Kakuros (like the 22 \times 14 one mentioned above) where the new model pays off are rare.

When to Use These Predicates?

circuit, subcircuit

lex_lesseq

regular, table

Checklist COCP/M4CO 3

Rapid prototyping of a new constraint predicate: The regular

and table predicates are very useful in the following conjunctive situation:

- A needed constraint predicate γ on a 1d array of decision variables is not a built-in of MiniZinc or the used solver.
- A definition of γ in terms of built-in predicates is not apparent to the modeller, or such a definition has turned out to inherit inference that either has too high time complexity or is too weak (or both).
- The modeller does not have the time or skill to design an inference algorithm for γ (to be seen for CP solvers in part 2 of course 1DL442), or deems γ not reusable for other problems.
- The time complexity and strength of an inference algorithm for γ are not deemed crucial for the time being.

Checklist COCP/M4CO 3

Important Modelling Idea

Example (Encoding a function on a small set)

The non-linear constraint x * x = y, where there is exactly one y for every x, may yield poor inference and become a bottleneck: for x only in 1..9, say, try element (x, [d*d | d in 1..9], y), where d*d is not non-linear, that is [d*d | d in 1..9][x] = y, for better inference and higher speed.

The element predicate is a specialisation of regular and table, just like a function is a special case of a relation:

Example (Encoding a relation over a small set)

The non-linear constraint x*x=abs(y), where there are two y for most x, may yield poor inference and become a bottleneck: for x only in 0..3, say, try the less readable table([x,y], [|0,0|1,-1|1,1|2,-4|2,4|3,-9|3,9|]) for better inference and higher speed (but maybe not with a MIP solver).

- 11 The predicates with the most specific semantics are used
- 12 Global constraints are not replaced by their definitions
- 13 Constraints over shared decision variables are ideally merged
- 14 The element predicate is not used explicitly, for clarity
- 15 Functions on small sets are encoded if needed by implicit element
- 16 Relations over small relations are encoded if needed by regular / table
