Örebro University, SWEDEN*

\* *Work funded by project SAUNA  
(Safe Autonomous Navigation)  
Coordinator: Dimiter Driankov*

## AGVs for Industrial Automation

- Autonomous Ground Vehicles (AGVs) becoming paramount to industrial automation

mining (e.g., Atlas-Copco)

construction (e.g., Volvo)

logistics (e.g., Kollmorgen)

- Several key processes are still ad-hoc and labor-intensive
  - AGV paths often pre-defined and hand-crafted
  - crude planning/allocation/scheduling heuristics
  - conflicts “avoided off-line” rather than resolved on-line
  - lack of **flexibility** and **reconfigurability**

## What If...

- Site operators could **post high-level requirements**
  - new tasks, vehicles  
*e.g., “pick up new incoming loads”*
  - spatial constraints  
*e.g., “zone A is now off-limits”*
  - temporal constraints  
*e.g., “complete mission of vehicle A within 10 minutes”*
- Vehicles could **adapt** their current and scheduled trajectories accordingly
  - vehicles coordinate automatically in response to posted requirements
- **Performance of vehicles** could be automatically taken into account by **other vehicles**

## The Core Issue of Coordination

- Coordination is necessary to ensure absence of **collisions** and **deadlocks**
- **Current practice:** compute trajectories for all vehicles **before** coordination occurs
  - collisions and deadlocks are dealt with locally
  - overall fleet requirements cannot be guaranteed
- **Our view:** all decisions regarding vehicle trajectories can be seen as **constraints on trajectories**
  - some constraints **known in advance**, some need to be **inferred**
- **Least commitment:** impose increasingly tight constraints on trajectory, but **do not commit** to specific solution until **execution**

# Outline

- 1 Trajectory Envelopes
- 2 Conflict Resolution as Refinement of Trajectory Envelopes
- 3 Control with Trajectory Envelopes
- 4 Evaluation
- 5 Conclusions

## Non-Holonomic Vehicles

- Vehicles are non-holonomic  $\Rightarrow$  no sideways motion
- “Car-like” vehicles

### Kinematic Model

$$\dot{q} = f(q, v) = (v \cos(\theta), v \sin(\theta), \frac{v}{l} \tan(\phi), \dot{\theta})$$

$$q = (x, y, \theta, \phi) \in \mathbb{R}^4 \text{ (state vector)}$$

$$v = (v, \dot{\theta}) \in \mathbb{R}^2 \text{ (control vector)}$$

- **Path:**  $p : [0, 1] \rightarrow \mathbb{R}^2$  (parametrized using arc length)
- **Trajectory:**  $p(\sigma(t))$  ( $\sigma$  = time history along path)

## Trajectories and Trajectory Envelopes (I)

- **Trajectory envelope: spatial** requirements on  $p$  and **temporal** requirements on  $\sigma(t)$ 
  - **temporal envelope, spatial envelope**

## Trajectories and Trajectory Envelopes (II)

- Trajectory  $p(\sigma(t))$  is **admissible** if
  - it can be obtained from the evolution of the **kinematic model**
  - $p / \sigma(t)$  lies within the **spatial / temporal** envelope

## Explicit Requirements as Constraints

- Avoiding **fixed obstacles** = imposing **spatial constraints** on trajectory envelopes
  - drivable area encoded as spatial constraints
  - any additional spatial requirements can be posted as well
- High-level **temporal requirements** = imposing **temporal constraints** on trajectory envelopes
  - deadlines, durations, and any other temporal requirements can be posted directly on trajectory envelopes
- We can constrain **admissible trajectories** to account for all high-level spatial and temporal requirements
  - however, **collisions** between vehicles and **deadlocks** are still possible. . .

## Computing Spatial Envelopes (I)

- Paths computed over drivable area using *ARA*\*
  - anytime path planning algorithm [Likhachev et al., 2003]
  - uses kinematically feasible motion primitives

## Computing Spatial Envelopes (I)

- Paths computed over drivable area using *ARA*\*
  - anytime path planning algorithm [Likhachev et al., 2003]
  - uses kinematically feasible motion primitives

## Computing Spatial Envelopes (I)

- Paths computed over drivable area using *ARA*\*
  - anytime path planning algorithm [Likhachev et al., 2003]
  - uses kinematically feasible motion primitives

## Computing Spatial Envelopes (II)

- Spatial envelopes computed over obtained paths
  - sample paths with given  $\Delta\sigma \propto (1/\text{curvature of the path})$
  - calculate polyhedron  $\mathcal{S}_i^{(j)}$  enclosing the sampled point

## Computing Temporal Envelopes

- Impose temporal bounds on **spatial envelope traversal**

$$\ell_i^{(j)} \leq e_i^{(j)} - s_i^{(j)} \leq u_i^{(j)}$$

$$\ell_{i,i+1}^{(j)} \leq e_i^{(j)} - s_{i+1}^{(j)} \leq u_{i,i+1}^{(j)}$$

- Bounds computed with **slowest** and **fastest** speed traversal of reference path

$$\ell_i = e_i^{\text{fast}} - s_i^{\text{slow}}, \quad u_i = e_i^{\text{slow}} - s_i^{\text{fast}},$$

$$\ell_{i,i+1} = e_i^{\text{fast}} - s_{i+1}^{\text{slow}}, \quad u_{i,i+1} = e_i^{\text{slow}} - s_{i+1}^{\text{fast}}$$

# Outline

- 1 Trajectory Envelopes
- 2 Conflict Resolution as Refinement of Trajectory Envelopes
- 3 Control with Trajectory Envelopes
- 4 Evaluation
- 5 Conclusions

# Spatio-Temporal Conflicts

- Polygons that overlap in **time** and **space** constitute a **conflict**
- **Eliminating the temporal overlap** resolves a conflict

- **Spatio-temporal** overlap:

$$\mathcal{S}_i^{(j)} \cap \mathcal{S}_k^{(m)} \neq \emptyset \wedge [s_i^{(j)}, e_i^{(j)}] \cap [s_k^{(m)}, e_k^{(m)}] \neq \emptyset$$

- Semantics of **temporal** overlap:

$$[s_i^{(j)}, e_i^{(j)}] \cap [s_k^{(m)}, e_k^{(m)}] \neq \emptyset \text{ if } \max(\underline{s}_i^{(j)}, \underline{s}_k^{(m)}) \leq \min(\underline{e}_i^{(j)}, \underline{e}_k^{(m)})$$

## Conflict Resolution as a Meta-CSP (I)

- Spatio-temporal conflicts solved by **posting temporal constraints** [Cesta et al., 2002]
  - remove temporal overlap between polygons
- Search for resolving constraints **cast as a CSP**
  - **variables:** pairs of spatio-temporally overlapping polygons
  - **values:** temporal constraints that eliminate temporal overlap
- Collisions are avoided by **refining the trajectory envelopes**
  - adding temporal constraints to eliminate temporal overlap
- **Note:** temporal envelope refinement can be alternated with **spatial envelope refinement**
  - adding spatial constraints to eliminate spatial overlap

## Conflict Resolution as a Meta-CSP (II)

- Search for resolving temporal constraints performed using standard backtracking search algorithm
- **Variable ordering heuristic** based on **spatial** features
  - prefer pairs of polygons that are **spatially closer** to other conflicting pairs
- **Value ordering heuristic** based on **temporal** features
  - prefer orderings that least impact overall **temporal flexibility**
- Conflict resolution also eliminates **deadlocks**
  - backtracking search breaks cycles on resource usage  
(resources = intersections of temporally overlapping polygons)

# Outline

- 1 Trajectory Envelopes
- 2 Conflict Resolution as Refinement of Trajectory Envelopes
- 3 Control with Trajectory Envelopes**
- 4 Evaluation
- 5 Conclusions

## From Trajectory Envelopes to Control Actions (I)

- Conflict resolution **refines the temporal envelope** to obtain conflict- and deadlock-free trajectory envelopes
- We now have available **many alternative trajectories** that can be sampled from these envelopes
  - spatial constraints designate the polygons in which vehicles should be
  - temporal constraints determine flexible bounds on each polygon

## From Trajectory Envelopes to Control Actions (II)

- Each vehicle has a **tracking controller**
  - computes **kinematically feasible** control actions for vehicle
  - minimizing divergence from a **reference trajectory**
  - while accounting for **spatial constraints**
  - based on efficient QP solver [Dimitrov et al., 2011]
- **Controller input = nominal path + fixed temporal bounds + spatial envelope**

## Sampling Trajectory Envelopes (I)

- Due to efficient formulation, controller can compute control actions for **several alternative** reference trajectories
  - **choose** “best” one to follow according to **tracking performance**
- Alternative bounds can be computed in **polynomial time**
  - controllers choose current alternative **consistently** w/ other vehicles (executed temporal profiles must be solution of the STP)

## Sampling Trajectory Envelopes (I)

- Due to efficient formulation, controller can compute control actions for **several alternative** reference trajectories
  - **choose** “best” one to follow according to **tracking performance**
- Alternative bounds can be computed in **polynomial time**
  - controllers choose current alternative **consistently** w/ other vehicles (executed temporal profiles must be solution of the STP)

## Sampling Trajectory Envelopes (I)

- Due to efficient formulation, controller can compute control actions for **several alternative** reference trajectories
  - **choose** “best” one to follow according to **tracking performance**
- Alternative bounds can be computed in **polynomial time**
  - controllers choose current alternative **consistently** w/ other vehicles (executed temporal profiles must be solution of the STP)

# Outline

- 1 Trajectory Envelopes
- 2 Conflict Resolution as Refinement of Trajectory Envelopes
- 3 Control with Trajectory Envelopes
- 4 Evaluation**
- 5 Conclusions

## Quantitative Evaluation on Artificial Problems

- 900 problems
- 9 test sets (2–10 vehicles)
- randomly generated paths
- 100 trials per test set
- Note: artificially difficult problems

# Quantitative Evaluation on Artificial Problems

- Average conflict resolution time < 1 sec with up to 8 vehicles
- Maximum time to calculate an alternative temporal profile < 50 msec

## Realistic Test Run

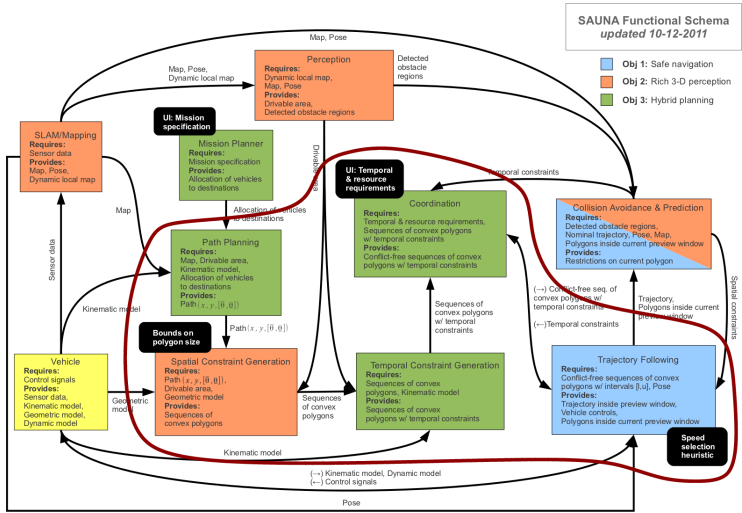

- 7 Linde vehicles, 140 polyhedra, pre-assigned start/destination poses
- Path planning: 5 sec / Conflict resolution: 34 sec (13 temporal constraints)
- Time to calculate alternative temporal profiles: 250 msec

# Conclusions

- Fleet management typically consists of **several processes**
  - all processes impose requirements on trajectories
- **Constraint-based formulation** provides processes with a **uniform model**
  - perception, planning, scheduling, control all contribute to refining trajectory envelopes
- Not all processes are necessarily **automated**
  - human operators, a pre-existing dispatching strategy, . . .
  - this is important for industrial application
- Modular approach maximizes the ability to **react at different levels**
  - modules impose increasingly low-level constraints on overall solution
  - commitment to specific trajectories done **as late as possible**

# SAUNA Functional View

Thank You!
